

Volumes

- on-disk files in a Container are ephemeral. All data stored inside a container is deleted if the container crashes. When a Container crashes, kubelet will restart it, but the files will be lost which means that it will not have any of the old data.
- To overcome this problem, Kubernetes uses Volumes. A Volume is essentially a directory backed by a storage medium. The storage medium, content and access mode are determined by the Volume Type.

Volume Types

Kubernetes supports several types of Volumes.

- emptyDir: An emptyDir volume is first created when a Pod is assigned to a Node and exists as long as that Pod is running on that node. As the name says, it is initially empty. When a Pod is removed from a node for any reason, the data in the emptyDir is deleted forever.
- hostPath: A hostPath volume mounts a file or directory from the host node's filesystem into your Pod. If the Pod is terminated, the content of the Volume is still available on the host.

Volume Types

- awsElasticBlockStore: An awsElasticBlockStore volume mounts an Amazon Web Services (AWS) EBS Volume into your Pod.
- azureDisk: An azureDisk is used to mount a Microsoft Azure Data Disk into a Pod.
- Secret: A secret volume is used to pass sensitive information, such as passwords, to Pods.

Volume Types

- **configMap:** The configMap resource provides a way to inject configuration data, or shell commands and arguments into a Pod.
- persistentVolumeClaim: A persistentVolumeClaim volume is used to mount a PersistentVolume into a Pod.

PersistentVolumeClaims

A **PersistentVolumeClaim (PVC)** is a request for storage by a user. Users request for PersistentVolume resources based on type, access mode, and size. There are three access modes:

- ReadWriteOnce (read-write by a single node)
- ReadOnlyMany (read-only by many nodes)
- ReadWriteMany (read-write by many nodes).
- Once a suitable PersistentVolume is found, it is bound to a PersistentVolumeClaim.
